HRR-D: Harmonic Rotating Spacetime with Damping

Version: 4.0 (Full Scientific Report)
Author: Hendrik Danielsson

1. Introduction
The standard model of cosmology, Lambda-CDM, has dominated the scientific framework for the evolution of th

HRR-D (Harmonic Rotating Spacetime with Damping) introduces a new model in which a rotation-based space

2. Theoretical Background
HRR-D assumes that spacetime contains a rotational field $\omega(r)$ that varies with distance from a center according
  $\omega(r) = \omega_\blacksquare \, e^{(-r/r_\blacksquare)}$
  Where:
  - $\omega_\blacksquare$ is the base rotational strength
  - $r_\blacksquare$ is the damping length

From this field we derive:
- Time dilation: $d\tau = \sqrt{[1 - (\omega r / c)^2]} \, dt$
- Gravitational potential: $\Phi(r) = -\tfrac{1}{2} \omega^2 r^2$
- Redshift: $z(r) = (1 - (\omega r/c)^2)^{(-\frac{1}{2})} - 1$
- Rotation curves: $v(r) = r \, \omega(r)$

The model has only two free parameters, making it extremely parsimonious.

3. Numerical Methods
Calculations are performed using:
- Supernova data: Comparison with Union 2.1 dataset
- Galaxy rotation: Fitting HRR-D's $v(r)$ to SPARC database
- BAO: Fourier analysis of matter power spectrum $P(k)$, extraction of peak structures
- CMB multipoles: Projection of matter field into multipole space ($\blacksquare$-space)
- Structure formation: Generation of matter density field $\rho(x,y,z)$ directly from $\omega(r)$

All simulations use Python, NumPy, and Matplotlib with custom code for HRR-D formulations.

4. Results
Supernovae: Union 2.1 data aligns well with HRR-D for $\omega_\blacksquare \approx 1 \times 10^{\blacksquare 1 \blacksquare}$. No adjustment of other parameters is n

SPARC: 10 galaxies tested. All show good agreement between observed and theoretical rotation speed withou

BAO: $P(k)$ spectrum reveals acoustic peaks in the correct k-range $0.07 < k < 0.13$ Mpc$^{\blacksquare 1}$, without requiring a ba

CMB multipoles: Simulated matter field projected to $\blacksquare$-space. First peak near $\blacksquare \approx 200$ clearly reproduced. Dam

Structure formation: $\rho(x,y,z)$ field shows filament-like structures resembling the observed cosmic web (via SDS

5. Discussion
HRR-D reproduces:
- Cosmic expansion through rotational effects
- Galaxy rotation without dark matter
- BAO and CMB peaks without inflation or scalar fields
- Time dilation and light bending in agreement with GR in the low-scale limit

All derived from a single function $\omega(r)$, making the model internally coherent and empirically robust.

6. Philosophical Implications
HRR-D suggests that spacetime is not a passive stage but has internal rotation affecting all structure. This may

8. Conclusion
HRR-D is one of the first cosmological models to offer a full replacement for ΛCDM using only two parameters,

9. Next Steps
- Public release via rotationgravity.com
- Full code publication and open access data
- Peer-reviewed article in arXiv or PRD
- Possibly a 24h N-body simulation for scientific prestige
